# 1 Introduction

This assignment involves working with three different datasets:

- **Dataset 1:** A medical biopsy dataset. The target variable (*Biopsy*) indicates whether a patient is **Healthy** or has **Cancer**.
- **Dataset 2:** A fetal health dataset. The target variable (*fetal\_health*) can have three classes (1, 2, 3).
- **Dataset 3:** A banking (marketing) dataset. The target variable (*y*) is binary (**yes** or **no**), indicating whether a customer subscribed to a term deposit.

The goal is to compare four classification algorithms on each dataset:

1. Decision Tree (Q1)
2. Random Forest (Q2)
3. XGBoost (Q3)
4. AdaBoost (Q4)

We evaluate each model using **5-fold cross-validation**, reporting:

- **Accuracy**
- **Precision**
- **Recall**
- **F1 Score**
- **AUC-ROC** (Area Under the ROC Curve)

Additionally, we plot:

- **ROC curves**
- **Decision boundaries** (by selecting any two features for a 2D visualization)

## 2 Data Preprocessing

For each dataset, we apply the following general steps:

1. **Loading and Concatenation (if needed):** For Dataset 2, for example, two partial CSV files are concatenated into a single DataFrame.
2. **Handling Missing Values:**
  - Replace non-numeric or "?" values with **NaN**.

- Impute NaN by the mean of the respective column.
3. **Feature Selection for Visualization (2D):** We select two features (e.g., `Age` vs. `Smokes (years)` in Dataset 1) for plotting the decision boundary.
  4. **Train-Test Split:** Usually, a portion (20%) is separated to evaluate or plot ROC. For 5-fold CV, the entire data is systematically split.
  5. **5-Fold Cross-Validation:**
    - Use `StratifiedKFold` with `n_splits=5` to preserve class distribution in each fold.
  6. **Metrics Calculation:**
    - Accuracy =  $\frac{TP+TN}{TP+TN+FP+FN}$
    - Precision =  $\frac{TP}{TP+FP}$
    - Recall =  $\frac{TP}{TP+FN}$
    - F1 =  $2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$
    - AUC-ROC via `roc_auc_score`, often using `predict_proba`.

## 3 Experiments and Results

We summarize the four classifiers below (Q1–Q4). The same methodology is applied to all three datasets.

### 3.1 Q1: Decision Tree Classifier

#### Dataset 1 (Biopsy):

- We fit a `DecisionTreeClassifier` using 5-fold cross-validation.
- For each fold, we compute Accuracy, Precision, Recall, F1 Score, and AUC-ROC.
- After cross-validation, we use a separate train/test split to plot the ROC curve and to visualize decision boundaries (using two selected features).

#### Dataset 2 (Fetal Health):

- Multi-class classification. We use `average='weighted'` for precision/recall/F1.
- For AUC-ROC, we use `roc_auc_score(..., multi_class='ovr')`.

#### Dataset 3 (Banking):

- Binary classification (`yes/no`).
- Similar approach: 5-fold CV, metrics, ROC plot, and 2D decision boundary (using two numeric features, e.g., `euribor3m` vs. `duration`).

### 3.2 Q2: Random Forest Classifier

The procedure is the same, except we use:

```
from sklearn.ensemble import RandomForestClassifier
clf = RandomForestClassifier(n_estimators=100, random_state=42)
```

We again do 5-fold CV on each dataset, collect metrics, plot ROC, and visualize 2D boundaries.

### 3.3 Q3: XGBoost Classifier

Using:

```
from xgboost import XGBClassifier
clf = XGBClassifier(random_state=42)
```

We replicate the same pipeline:

- 5-fold CV (stratified).
- Evaluate all metrics.
- Plot ROC curves (multi-class for Dataset 2, binary for Datasets 1 and 3).
- Plot 2D decision boundaries with selected features.

### 3.4 Q4: AdaBoost Classifier

Using:

```
from sklearn.ensemble import AdaBoostClassifier
clf = AdaBoostClassifier(random_state=42)
```

Again, we use the same methodology of cross-validation, metrics, ROC, and decision boundaries.

## 4 Illustrative Results

Although your results will vary, an example of average (5-fold) performance metrics might look like this:

(These figures are only examples. You would replace them with the actual results from your code.)

Table 1: Illustrative Cross-Validation Results

| Classifier    | Dataset   | Accuracy | Precision | Recall | F1   | AUC-ROC    |
|---------------|-----------|----------|-----------|--------|------|------------|
| Decision Tree | Dataset 1 | 0.90     | 0.88      | 0.92   | 0.90 | 0.93       |
| Decision Tree | Dataset 2 | 0.91     | 0.90      | 0.89   | 0.89 | 0.90 (ovr) |
| Decision Tree | Dataset 3 | 0.88     | 0.85      | 0.84   | 0.84 | 0.89       |
| Random Forest | Dataset 1 | 0.93     | 0.91      | 0.95   | 0.93 | 0.96       |
| Random Forest | Dataset 2 | 0.94     | 0.93      | 0.92   | 0.92 | 0.95 (ovr) |
| Random Forest | Dataset 3 | 0.90     | 0.88      | 0.87   | 0.87 | 0.91       |
| XGBoost       | Dataset 1 | 0.94     | 0.93      | 0.96   | 0.94 | 0.96       |
| XGBoost       | Dataset 2 | 0.95     | 0.94      | 0.93   | 0.94 | 0.96 (ovr) |
| XGBoost       | Dataset 3 | 0.91     | 0.89      | 0.89   | 0.89 | 0.92       |
| AdaBoost      | Dataset 1 | 0.91     | 0.89      | 0.92   | 0.90 | 0.94       |
| AdaBoost      | Dataset 2 | 0.93     | 0.92      | 0.90   | 0.91 | 0.94 (ovr) |
| AdaBoost      | Dataset 3 | 0.89     | 0.86      | 0.84   | 0.85 | 0.90       |

## 5 Conclusion

In this assignment, we implemented and compared four classification algorithms—Decision Tree, Random Forest, XGBoost, and AdaBoost—on three distinct datasets. We used 5-fold cross-validation to compute:

- Accuracy
- Precision
- Recall
- F1 Score
- AUC-ROC

Additionally, we plotted ROC curves and generated 2D decision boundary visualizations (by selecting two numeric features at a time). The experiments suggest that ensemble methods (Random Forest, XGBoost, AdaBoost) typically outperform a single decision tree on average. However, the ideal choice depends on hyperparameter tuning, data characteristics, and class imbalances.
